2. Selecting.....	2
3. Pandas filtering methods.....	3
4. Updating values.....	3
5. Working with strings.....	3
6. Grouping and merging.....	4
7. Plotting.....	4
8. Functions.....	4

1. Basics

Make a DataFrame	<code>pd.DataFrame(your_data)</code>
Make a Series	<code>pd.Series(your_data)</code>
Summary information	<code>df.info()</code>
# of rows, # of columns	<code>df.shape</code>
Descriptive statistics	<code>df.describe()</code>
First rows	<code>df.head()</code>
Last rows	<code>df.tail()</code>
All column labels	<code>df.columns</code>
All index labels or Index range	<code>df.index</code>
Check for null values	<code>df.isnull()</code> or <code>df.isna()</code>

2. Selecting

One column	<code>df [column]</code>
Multiple columns	<code>df [[column1, column2,...]]</code>
By labels	<code>df.loc [index_label(s), column_label(s)]</code>
By positions	<code>df.iloc [index_position(s), column_position(s)]</code>

3. Pandas filtering methods

Unique values in a column	<code>df [column].unique()</code>
Match one of multiple values	<code>df [column].isin([value1, value2,...])</code>
Match within a range	<code>df [column].between(low_value, high_value)</code>
Filter by condition	<code>df.loc [boolean_mask]</code> or <code>df.query('boolean statement')</code>
Sort and select for greatest “n” values in column	<code>df.nlargest(n, column)</code>
Sort and select for least “n” values in column	<code>df.nsmallest(n, column)</code>

4. Updating values

Remove rows with missing values	<code>df.dropna()</code>
Remove rows with duplicate values	<code>df.drop_duplicates()</code>
Alter column to have data_type	<code>df [column].astype(data_type)</code>
Convert column to numeric type	<code>pd.to_numeric(df [column])</code>
Sort rows by column's values	<code>df.sort_values(column)</code>
Remove row(s) or column(s) by label(s)	<code>df.drop()</code>
Create new column	<code>df [new_column] = some_value(s)</code>
Combine two DataFrame	<code>pd.concat([df1, df2])</code>
Assign value to specific cell(s)	<code>df.loc [row label or condition, column] = value</code> or <code>df.iloc [row position, column position] = value</code>
Assign value to column cells <i>not</i> meeting condition	<code>df [column].where(condition, value)</code>
Reassign many different values and / or Reassign values with pattern matching	<code>df.replace()</code>

5. Working with strings

Perform string method on values in column	<code>df [column].str.method()</code>
---	---

6. Grouping and merging

Group column1 and aggregate column2	<code>df.groupby(column1)[column2].method()</code>
Group column and perform many aggregates	<code>df.groupby(column).agg()</code>
Merge two DataFrame on specified columns	<code>df1.merge(df2, left_on=column_df1, right_on=column_df2, how='inner'/'left'/'right')</code>

7. Plotting

Create histogram of one column	<code>df [column].hist()</code>
Create bar plot of column frequency	<code>freq = df [column].value_counts() freq.plot.bar()</code>
Create scatter plot comparing two columns	<code>df.plot.scatter(x=column1, y=column2)</code>

8. Functions

Define function	<code>def function_name(arg1, arg2,...): code code return output</code>
Call function	<code>function_name(arg1, arg2,...)</code>
